A RELATION FOR GROMOV–WITTEN INVARIANTS OF LOCAL CALABI–YAU THREEFOLDS

SIU-CHEONG LAU, NAICHUNG CONAN LEUNG AND BAosen WU

Abstract. We compute certain open Gromov–Witten invariants for toric Calabi–Yau threefolds. The proof relies on a relation for ordinary Gromov–Witten invariants for threefolds under certain birational transformation, and a recent result of Kwokwai Chan.

1. Introduction

The aim of this paper is to compute genus zero open Gromov–Witten invariants for toric Calabi–Yau threefolds, through a relation between ordinary local Gromov–Witten invariants of the canonical line bundle $K_S$ of a projective surface $S$ and the canonical bundle $K_{S_n}$ of a blow-up $S_n$ of $S$ at $n$ points.

The celebrated SYZ mirror symmetry was initiated from the work of Strominger et al. [19]. It successfully explains mirror symmetry when there is no quantum correction [15, 18]. It also works nicely for toric Fano manifolds [5]. Quantum corrections are involved in this case, which are the open Gromov–Witten invariants counting holomorphic disks bounded by Lagrangian torus fibers. Cho and Oh [7] classified such holomorphic disks and computed the mirror superpotential. However, when the toric manifold is not Fano, the moduli of holomorphic disks may contain bubble configurations, leading to a nontrivial obstruction theory. The only known results are the computations of the mirror superpotentials of Hirzebruch surface $F_2$ by Fukaya et al.’s [9] using their big machinery, and $F_2$ and $F_3$ by Auroux’s [1] via wall-crossing technique (see also the excellent paper [2]).

Our first main result Theorem 4.1 identifies genus zero open Gromov–Witten invariants with ordinary Gromov–Witten invariants of another Calabi–Yau threefold. As an illustration, we state its corollary for the case of canonical line bundles of toric surfaces, avoiding technical terms at the moment.

Theorem 1.1 (Corollary of Theorem 4.1). Let $S$ be a smooth toric projective surface with canonical line bundle $K_S$, which is itself a toric manifold. Let $L \subset K_S$ be a Lagrangian toric fiber, which is a regular fiber of the moment map on $K_S$ equipped with a toric Kähler form. We denote by $\beta \in \pi_2(K_S, L)$ the class represented by a holomorphic disk whose image lies in a fiber of $K_S \to S$. For any class $\alpha \in H_2(S, \mathbb{Z})$ represented by a curve $C \subset S$, we let $\alpha' \in H_2(\tilde{S}, \mathbb{Z})$ be the class represented by the proper transform of $C$, where $\tilde{S}$ is the blow-up of $S$ at one point.

Let $n_{\beta+\alpha}$ be the one-point genus zero open Gromov–Witten invariant of $(K_S, L)$ (see equation (4) for its definition), and $(1)^{K_{S_n}}_{0,0,\alpha'}$ be genus zero Gromov–Witten
invariant of $K_S$ (see equation (2) for its definition). Suppose $\tilde{S}$ is Fano. Then

$$n_{\beta+\alpha} = \langle 1 \rangle_{0,0,\alpha'}^{K_S}.$$ 

This result is used to derive open Gromov–Witten invariants in a recent paper [4] on the SYZ program for toric Calabi–Yau manifolds. We prove Theorem 4.1 using our second main result stated below and a generalized version of Chan’s result [3] relating open and closed Gromov–Witten invariants.

Let $S$ be a smooth projective surface and $X = P(\mathcal{K}_S \oplus \mathcal{O}_S) \rightarrow S$ be the fiberwise compactification of the canonical line bundle $K_S$. Let $S_n$ be the blowup of $S$ at $n$ distinct points, and $W = P(K_{S_n} \oplus \mathcal{O}_{S_n})$ be the fiberwise compactification of $K_{S_n}$. We relate certain $n$-point Gromov–Witten invariants of $X$ to Gromov–Witten invariants of $W$ without point condition.

**Theorem 1.2.** Let $X$ and $W$ be defined above. Let $h \in H_2(X,\mathbb{Z})$ be the fiber class of $X \rightarrow S$ and $\alpha \in H_2(S,\mathbb{Z})$ viewed as a class in $H_2(X,\mathbb{Z})$ via the zero-section embedding $S = P(0 \oplus \mathcal{O}_S) \rightarrow X$. Then for any $n \geq 0$ we have

$$\langle [pt],\ldots,[pt]\rangle_{0,n,\alpha+nh}^X = \langle 1 \rangle_{0,0,\alpha'}^W,$$

where $[pt] \in H^6(X,\mathbb{Z})$ is the Poincaré dual of the point class, and $\alpha' \in H_2(S,\mathbb{Z})$ is the proper transform of $\alpha$.

Now we outline the proof of Theorem 1.2 in the case $n = 1$. Fix a generic fiber $H$ of $X$. Let $x$ be the intersection point of $H$ with the divisor at infinity $P(\mathcal{K}_S \oplus 0) \subset X$. We construct a birational map $f : X \dashrightarrow \tilde{X} \rightarrow W$ so that $\pi_1$ is the blowup at $x$, and $\pi_2$ is a simple flop along $\tilde{H}$, which is the proper image of $H$ under $\pi_1$. We compare Gromov–Witten invariants of $X$ and $W$ through the intermediate space $\tilde{X}$. Equality (1) follows from the results of Gromov–Witten invariants under birational transformations listed in Section 2.

We remark that Theorem 1.2 is a corollary of Proposition 3.1, which holds for all genera. They can be generalized to the case when $K_S$ is replaced by other local Calabi–Yau threefolds, as we shall explain in Section 3.

This paper is organized as follows. Section 2 serves as a brief review on definitions and results that we need in Gromov–Witten theory. In Section 3, we prove Theorem 1.2 and its generalization to quasi-projective threefolds. In Section 4, we deal with toric Calabi–Yau threefolds and prove Theorem 4.1. Finally in Section 5, we generalize Theorem 1.2 to $\mathbb{P}^n$-bundles over an arbitrary smooth projective variety.

## 2. Gromov–Witten invariants under birational maps

In this section, we review Gromov–Witten invariants and their transformation under birational maps.

Let $X$ be a smooth projective variety. Let $\overline{M}_{g,n}(X,\beta)$ be the moduli space of stable maps $f : (C;x_1,\ldots,x_n) \rightarrow X$ with genus $g(C) = g$ and $[f(C)] = \beta \in H_2(X,\mathbb{Z})$. Let $\text{ev}_i : \overline{M}_{g,n}(X,\beta) \rightarrow X$ be the evaluation maps at marked points $f \mapsto f(x_i)$. The genus $g$ $n$-pointed Gromov–Witten invariant for classes $\gamma_i \in H^\bullet(X)$, $i = 1,\ldots,n$, is defined as

$$\langle \gamma_1,\cdots,\gamma_n \rangle_{g,n,\beta}^X = \int_{[\overline{M}_{g,n}(X,\beta)]_{\text{vir}}} \prod_{i=1}^n \text{ev}_i^*(\gamma_i).$$
When the expected dimension of $\overline{M}_{g,n}(X,\beta)$ is zero, for instance, when $X$ is a Calabi–Yau threefold and $n=0$, we will be interested primarily in the invariant
\begin{equation}
\langle 1 \rangle^X_{g,0,\beta} = \int_{[\overline{M}_{g,0}(X,\beta)]^{\text{vir}}} 1,
\end{equation}
which equals to the degree of the 0-cycle $[\overline{M}_{g,0}(X,\beta)]^{\text{vir}}$ of $\overline{M}_{g,0}(X,\beta)$.

Roughly speaking, the invariant $\langle \gamma_1, \ldots, \gamma_n \rangle^X_{g,n,\beta}$ is a virtual count of genus $g$ curves in the class $\beta$ which intersect with generic representatives of the Poincaré dual $PD(\gamma_i)$ of $\gamma_i$. In particular, if we want to count curves in a homology class $\beta$ passing through a generic point $x \in X$, we simply take some $\gamma_i$ to be $[pt]$, the Poincaré dual of a point. In the genus zero case, there is an alternative way to do this counting: let $\pi : \tilde{X} \to X$ be the blow-up of $X$ at one point $x$; we count curves in the homology class $\pi^!(\beta) - e$, where $\pi^!(\beta) = PD(\pi^*PD(\beta))$ and $e$ is the line class in the exceptional divisor. By the result of Hu [13] (or the result of Gathmann [12] independently), this gives the desired counting:

**Theorem 2.1** ([12, 13]). Let $\pi : \tilde{X} \to X$ be the blow-up of $X$ at one point. Let $e$ be the line class in the exceptional divisor. Let $\beta \in H_2(X,\mathbb{Z}), \gamma_1, \ldots, \gamma_n \in H^*(X)$. Then we have
\begin{equation}
\langle \gamma_1, \ldots, \gamma_n, [pt] \rangle^X_{0,n+1,\beta} = \langle \pi^*\gamma_1, \ldots, \pi^*\gamma_n \rangle^\tilde{X}_{0,n,\pi^!(\beta) - e}
\end{equation}
where $\pi^!(\beta) = PD(\pi^*PD(\beta))$.

Another result that we need is the transformation of Gromov–Witten invariants under flops.

Let $f : X \dashrightarrow X_f$ be a simple flop between two threefolds along a smooth $(-1, -1)$ rational curve. There is a natural isomorphism
\begin{equation}
\varphi : H_2(X,\mathbb{Z}) \to H_2(X_f,\mathbb{Z}).
\end{equation}
Suppose that $\Gamma$ is an exceptional curve in $X$ and $\Gamma_f$ is the corresponding exceptional curve in $X_f$. Then
\begin{equation}
\varphi([\Gamma]) = -[\Gamma_f].
\end{equation}

The following theorem is proved by Li and Ruan [17].

**Theorem 2.2** ([17]). Let $f : X \dashrightarrow X_f$ be a simple flop between threefolds and $\varphi$ be the isomorphism given above. If $\beta \neq m[\Gamma] \in H_2(X,\mathbb{Z})$ for any exceptional curve $\Gamma$ and $\gamma_i \in H^*(X_f)$, we have
\begin{equation}
\langle \varphi^*\gamma_1, \ldots, \varphi^*\gamma_n \rangle^X_{g,n,\beta} = \langle \gamma_1, \ldots, \gamma_n \rangle^{X_f}_{g,n,\varphi(\beta)}.
\end{equation}

### 3. Gromov–Witten invariants of projectivization of $K_S$

We are now ready to prove Theorem 1.2 and its generalization to certain quasi-projective threefolds.

Let $S$ be a smooth projective surface. The fiberwise compactification $p : X = \mathbb{P}(K_S \oplus \mathcal{O}_S) \to S$ is a $\mathbb{P}^1$-bundle. We embed $S$ into $X$ as the zero section of the bundle $K_S$, i.e., $S = \mathbb{P}(0 \oplus \mathcal{O}_S) \subset X$. We denote $S^+ := \mathbb{P}(K_S \oplus 0) \subset X$ be the section at infinity of $p : X \to S$, and let $h$ be the fiber class of $p$. Then any class $\beta \in H_2(X,\mathbb{Z})$ which is represented by a holomorphic curve can be written as $\alpha + nh$, where $n$ is the intersection number of $\beta$ with the infinity section $S^+$, and $p_*(\beta) = \alpha \in H_2(S,\mathbb{Z})$. By
Riemann–Roch theorem, the expected dimension of $\overline{M}_{0,n}(X, \beta)$ is $3n$. One has the Gromov–Witten invariant

$$\langle [pt], \ldots, [pt] \rangle_{0,n, \beta}^X,$$

which counts rational curves in the class $\beta$ passing through $n$ generic points.

Let $x_1, \ldots, x_n$ be $n$ distinct points in $X$ and $y_i = p(x_i) \in S$. Consider the blow-up $\pi : S_n \to S$ of $S$ along the points $y_1, \ldots, y_n$ with exceptional divisors $e_1, \ldots, e_n$. For $\alpha \in H_2(S, \mathbb{Z})$, we let $\beta' \in H_2(S_n, \mathbb{Z})$ to be the class $\pi^* \alpha - \sum^n_{i=1} e_i$, which is called the strict transform of $\alpha$. When $\alpha$ is represented by some holomorphic curve $C$, $\beta'$ is the class represented by the strict transform of $C$ under the blowup $\pi$.

Let $W = \mathbb{P}(K_{S_n} \oplus \mathcal{O}_{S_n})$ be the fiberwise compactification of $K_{S_n}$. Then $\beta'$ defined above is a homology class of $W$ since $S_n \subset W$. The moduli space $\overline{M}_{0,0}(W, \beta')$ has expected dimension zero, we get the Gromov–Witten invariant $\langle 1 \rangle_{0,0, \beta'}^W$.

**Proposition 3.1.** Let $S$ be a smooth projective surface. Denote $p : X = \mathbb{P}(K_S \oplus \mathcal{O}_S) \to S$. Let $X_1$ be the blowup of $X$ at a point $x$ on the infinity section of $X \to S$. Let $W = \mathbb{P}(K_{S_1} \oplus \mathcal{O}_{S_1})$ where $\pi : S_1 \to S$ is the blowup of $S$ at the point $y = p(x)$. Then $W$ is a simple flop of $X_1$ along the proper transform $\hat{H}$ of the fiber $H$ through $x$.

**Proof.** Since $\hat{H}$ is the proper transform of $H$ under the blowup $\pi_1 : X_1 \to X$ at $x$, $\hat{H}$ is isomorphic to $\mathbb{P}^1$ with normal bundle $\mathcal{O}(-1) \oplus \mathcal{O}(-1)$. We have a simple flop $f : X_1 \dashrightarrow X'$ along $\hat{H}$. Next we show that $X' \cong W$. To this end, we use an alternative way to describe the birational map $f \pi_1^{-1} : X \dashrightarrow X'$.

It is well known that a simple flop $f$ is a composite of a blowup and a blowdown. Let $\pi_2 : X_2 \to X_1$ be the blowup of $X_1$ along $\hat{H}$ with exceptional divisor $E_2 \cong \hat{H} \times \mathbb{P}^1$. Because the restriction of normal bundle of $E_2$ to $\hat{H}$ is $\mathcal{O}(-1)$, we can blow down $X_2$ along the $\hat{H}$ fiber direction of $E_2$ to get $\pi_3 : X_2 \to X'$. Of course we have $f = \pi_3 \pi_2^{-1}$ and $\pi_3 \pi_2^{-1} \pi_1^{-1} : X \dashrightarrow X'$.

Notice that the composite $\pi_2^{-1} \pi_1^{-1} : X \dashrightarrow X_2$ can be written in another way. Let $\rho_1 : Z_1 \to X$ be the blowup of $X \to H$ with exceptional divisor $E'$. Let $F$ be the inverse image $\rho_1^{-1}(x)$. Then $F \cong \mathbb{P}^1$. Next we blow up $Z_1$ along $F$ to get $\rho_2 : Z_2 \to Z_1$. It is straightforward to verify that $Z_2 = X_2$ and $\rho_1 \rho_2 = \pi_1 \pi_2$. Thus we have $\pi_3 \pi_2^{-1} \pi_1^{-1} = \pi_3 (\rho_1 \rho_2)^{-1} : X \dashrightarrow X'$, from which it follows easily that $X' \cong W$. \hfill $\square$

**Corollary 3.1.** With notations as in the proposition, and let $e_1$ be the exceptional curve class of $\pi$, we have

$$\langle 1 \rangle_{g,0, \beta}^X = \langle 1 \rangle_{g,0, \beta'}^W,$$

where $\beta = \alpha + k\hat{H}$ and $\beta' = \pi' \alpha - ke_1$ for any nonzero $\alpha \in H_2(S, \mathbb{Z})$.

**Proof.** From the proposition, we know there is a flop $f : X_1 \dashrightarrow W$. Applying Theorem 2.2 to the flop $f$, since $\varphi([\hat{H}]) = -e_1$, we get

$$\varphi(\beta) = \varphi((\pi_1 \alpha) + [k\hat{H}]) = \pi' \alpha - ke_1 = \beta'.$$

Then (3) follows directly. \hfill $\square$

When $S_1$ is a Fano surface, $K_{S_1}$ is a local Calabi–Yau threefold and curves inside $S_1$ can not be deformed away from $S_1$. Indeed any small neighborhood $N_{S_1}$ of $S_1$ (resp. $N_{S \cup C}$ of $S \cup C$) inside any Calabi–Yau threefold has the same property. Here
C is a \((-1, -1)\)-curve, which intersects \(S\) transversely at a single point. Therefore we can define local Gromov–Witten invariants for \(N_{S_1}\) and \(N_{S \cup C}\). Using a canonical identification,

\[
H_2(S_1) \simeq H_2(S) \oplus \mathbb{Z} \langle e_1 \rangle \simeq H_2(S \cup C),
\]

the above corollary implies that the local Gromov–Witten invariants for local Calabi–Yau threefolds \(N_{S_1}\) and \(N_{S \cup C}\) are the same. When the homology class in \(S_1\) does not have \(e_1\)-component, this becomes simply the local Gromov–Witten invariants for \(N_S\).

This last relation for Gromov–Witten invariants of \(\text{Calabi–Yau threefolds}\) was first observed by Chiang et al. [6] in the case \(S\) is \(\mathbb{P}^2\) and genus is zero by explicit calculations.

These results can be generalized to the case when \(K_S\) is replaced by other local Calabi–Yau threefolds. The illustration of such a generalization is given at the end of this section.

Now we prove Theorem 1.2, that is

\[
\langle [\text{pt}], \ldots, [\text{pt}] \rangle^X_{0, n, \beta} = \langle 1 \rangle^W_{0, 0, \beta'}.
\]

**Proof of Theorem 1.2.** First, we assume \(n = 1\), that is, \(\pi : S_1 \to S\) is a blowup of \(S\) at one point \(y\) with exceptional curve class \(e_1\) and \(W = \mathbb{P}(K_{S_1} \oplus \mathcal{O}_{S_1})\). We need to show that

\[
\langle [\text{pt}] \rangle^X_{0, 1, \beta} = \langle 1 \rangle^W_{0, 0, \beta'},
\]

where \(\beta = \alpha + h\) and \(\beta' = \pi_1^\ast \alpha - e_1\).

Applying Theorem 2.1 to \(\pi_1 : X_1 \to X\), and notice that

\[
\pi_1^\ast (\beta) - e = \pi_1^\ast (\alpha + h) - e = \pi_1^\ast \alpha + [\tilde{H}],
\]

which we denote by \(\beta_1\), we then have \(\langle [\text{pt}] \rangle^X_{0, 1, \beta} = \langle 1 \rangle^X_{0, 0, \beta_1}\). Next we apply Proposition 3.1 for \(k = 1\), we get

\[
\langle 1 \rangle^X_{0, 0, \beta_1} = \langle 1 \rangle^W_{0, 0, \beta'},
\]

which proves the result for \(n = 1\).

For \(n > 1\), we simply apply the above procedure successively.

In particular, when \(S = \mathbb{P}^2\) and \(n = 1\), \(S_1\) is the Hirzebruch surface \(\mathbb{F}_1\). We use \(\ell\) to denote the line class of \(\mathbb{P}^2\). The class of exceptional curve \(e\) represents the unique minus one curve in \(\mathbb{F}_1\) and \(f = \pi_1^\ast \ell - e\) is its fiber class. In this case, the corresponding class \(\beta' = k\pi_1^\ast \ell - e = (k - 1)e + kf\). The values of \(N_{0, \beta'}\) have been computed in [6].

Starting with \(k = 1\), they are \(-2, 5, -32, 286, -3038, 35870\). (See Table 1.)

We remark that Theorem 1.2 can be generalize to quasi-projective threefolds with properties we describe below. Let \(X\) be a smooth quasi-projective threefold. Assume there is a distinguished Zariski open subset \(U \subset X\), so that \(U\) is isomorphic to the canonical line bundle \(K_S\) over a smooth projective surface \(S\), and there is a Zariski open subset \(S' \subset S\), so that each fiber \(F\) of \(K_S\) over \(S'\) is closed in \(X\). Typical examples of such threefolds include a large class of toric Calabi–Yau threefolds.

Theorem 1.2 still holds for such threefolds, provided that the blow-up of the surface \(S\) mentioned above at a generic point is Fano. Since we will not use this generalization in the paper, we only sketch the proof.

First, we construct a partial compactification $\bar{X}$ of $X$. Given a generic point $x \in U$, we have a unique fiber through $x$, say $H$. Let $\{y\} = H \cap S$. Take a small open neighborhood $y \in V$, we compactify $K_V$ along the fiber by adding a section at infinity as we did before. We call the resulting variety by $\bar{X}$.

The Gromov–Witten invariant $\langle [pt]\rangle_{0,1,\beta}^{\bar{X}}$ is well defined. Indeed, let $\beta \in H_2(\bar{X}, \mathbb{Z})$; and suppose $\beta = \alpha + [H]$ for some $\alpha$ in $H_2(S, \mathbb{Z})$. The moduli space of genus zero stable maps to $\bar{X}$ representing $\beta$ and passing through the generic point $x$ is compact since $S$ is Fano. Then the invariants can be defined as before.

To show the equality $\langle [pt]\rangle_{0,1,\beta}^{\bar{X}} = \langle 1 \rangle_{0,0,\beta'}^S$, we construct a birational map $f: \bar{X} \to W$ as in the proof of Theorem 1.2. Let $\tilde{S} \subset W$ be the image of $S$. Then $\tilde{S}$ is the blowup of $S$ at $y$. Let $\beta' \in H_2(\tilde{S}, \mathbb{Z})$ be the strict transform of $\alpha$. Since $\tilde{S}$ is Fano, we can define local Gromov–Witten invariant $\langle 1 \rangle_{0,0,\beta'}^S$. The equality follows directly as in the proof of Theorem 1.2.

4. Toric Calabi–Yau threefolds

In this section, we study open Gromov–Witten invariants of a toric Calabi–Yau manifold and prove our main Theorem 4.1. As an application, we show that certain open Gromov–Witten invariants for toric Calabi–Yau threefolds can be computed via local mirror symmetry.

First, we recall the standard notations. Let $N$ be a lattice of rank 3, $M$ be its dual lattice, and $\Sigma_0$ be a strongly convex simplicial fan supported in $N_\mathbb{R}$, giving rise to a toric variety $X_0 = X_{\Sigma_0}$. ($\Sigma_0$ is ‘strongly convex’ means that its support $|\Sigma_0|$ is convex and does not contain a whole line through the origin.) Denote by $v_i \in N$ the primitive generators of rays of $\Sigma_0$, and denote by $D_i$ the corresponding toric divisors for $i = 0, \ldots, m - 1$, where $m \in \mathbb{Z}_{\geq 3}$ is the number of such generators.

Calabi–Yau condition for $X_0$: There exists $\nu \in M$ such that $(\nu, v_i) = 1$ for all $i = 0, \ldots, m - 1$.

By fixing a toric Kaehler form $\omega$ on $X_0$, we have a moment map $\mu: X_0 \to P_0$, where $P_0 \subset M_\mathbb{R}$ is a polyhedral set defined by a system of inequalities

$$(v_j, \cdot) \geq c_j$$
for \( j = 0, \ldots, m - 1 \) and suitable constants \( c_j \in \mathbb{R} \). (Figure 2 shows two examples of toric Calabi–Yau varieties.)

Let \( L \subset X_0 \) be a regular fiber of \( \mu \), and \( \pi_2(X_0, L) \) be the group of disk classes. For \( b \in \pi_2(X_0, L) \), the most important classical quantities are the area \( \int_b \omega \) and the Maslov index \( \mu(b) \). By [7], \( \pi_2(X_0, L) \) is generated by basic disk classes \( \beta_i \) for \( i = 0, \ldots, m - 1 \), where each \( \beta_i \) corresponds to the ray generated by \( v_i \).

Other than these two classical quantities, one has the one-pointed genus-zero open Gromov–Witten invariant associated to \( b \) defined by Fukaya et al. [8] as follows. Let \( \overline{M}_1(X_0, b) \) be the moduli space of stable maps from bordered Riemann surfaces of genus zero with one boundary marked point to \( X_0 \) in the class \( b \), and denote by \( [\overline{M}_1(X_0, b)] \) its virtual fundamental class. One has the evaluation map \( \text{ev} : \overline{M}_1(X_0, b) \to L \). The one-pointed open Gromov–Witten invariant associated to \( b \) is defined as

\[
(4) \quad n_b := \int_{[\overline{M}_1(X_0, b)]} \text{ev}^*[\text{pt}],
\]

where \( [\text{pt}] \in H^n(L) \) is the Poincaré dual of a point in \( L \). Since the expected dimension of \( \overline{M}_1(X_0, b) \) is \( \mu(b)+n-2 \) and \( \text{ev}^*[\text{pt}] \) is of degree \( n \), \( n_b \) is non-zero only when \( \mu(b) = 2 \).

To investigate genus zero open Gromov–Witten invariants of a toric Calabi–Yau manifold \( X_0 \), we’ll need the following simple lemma for rational curves in toric varieties:

**Lemma 4.1.** Let \( Y \) be a toric variety which admits \( \nu \in M \) such that \( \nu \) defines a holomorphic function on \( Y \) whose zeros contain all toric divisors of \( Y \). Then the image of any non-constant holomorphic map \( u : \mathbb{P}^1 \to Y \) lies in the toric divisors of \( Y \). In particular, this holds for a toric Calabi–Yau variety.

**Proof.** Denote the holomorphic function corresponding to \( \nu \in M \) by \( f \). Then \( f \circ u \) gives a holomorphic function on \( \mathbb{P}^1 \), which must be a constant by maximal principle. \( f \circ u \) cannot be constantly non-zero, or otherwise the image of \( u \) lies in \((\mathbb{C}^\times)^n \subset Y \), forcing \( u \) to be constant. Thus \( f \circ u \equiv 0 \), implying the image of \( u \) lies in the toric divisors of \( Y \).

For a toric Calabi–Yau variety \( X_0 \), \( (\nu, v_i) = 1 > 0 \) for all \( i = 0, \ldots, m - 1 \) implies that the meromorphic function corresponding to \( \nu \) indeed has no poles. \( \square \)

As a consequence to the above lemma, we have the following:

**Proposition 4.1.** Assume the notations introduced above. For a disk class \( b \in \pi_2(X_0, L) \) which has Maslov index two, \( \overline{M}_1(X_0, b) \) is empty unless

1. \( b = \beta_i \) for some \( i \); or
2. \( b = \beta_i + \alpha \), where the corresponding toric divisor \( D_i \) is compact and \( \alpha \in H_2(X_0, \mathbb{Z}) \) is represented by a rational curve.

**Proof.** By Theorem 11.1 of [8], \( \overline{M}_1(X_0, b) \) is empty unless \( b = \sum_i k_i \beta_i + \sum_j \alpha_j \) where \( k_i \in \mathbb{Z}_{\geq 0} \) and each \( \alpha_j \in H_2(X_0, \mathbb{Z}) \) is realized by a holomorphic sphere. Since \( X_0 \) is Calabi–Yau, every \( \alpha_j \) has Chern number zero. Thus

\[
2 = \mu(b) = \sum_i k_i \mu(\beta_i) = \sum_i 2k_i,
\]
where $\mu(b)$ denotes the Maslov index of $b$. Thus $b = \beta_i + \alpha$ for some $i = 0, \ldots, m-1$ and $\alpha \in H_2(X_0, \mathbb{Z})$ is realized by some chains $Q$ of non-constant holomorphic spheres in $X_0$.

Now suppose that $\alpha \neq 0$, and so $Q$ is not a constant point. By Lemma 4.1, $Q$ must lie inside $\bigcup_{i=0}^{m-1} D_i$. $Q$ must have non-empty intersection with the holomorphic disk representing $\beta_i \in \pi_2(X_0, L)$ for generic $L$, implying some components of $Q$ lie inside $D_i$ and have non-empty intersection with the torus orbit $(\mathbb{C}^\times)^2 \subset D_i$. But if $D_i$ is non-compact, then the fan of $D_i$ (as a toric manifold) is simplicial convex incomplete, and so $D_i$ is a toric manifold satisfying the condition of Lemma 4.1. Then $Q$ has empty intersection with the open orbit $(\mathbb{C}^\times)^2 \subset D_i$, which is a contradiction.

It was shown in [7, 8] that $n_b = 1$ for basic disc classes $b = \beta_i$. The remaining task is to compute $n_b$ for $b = \beta_i + \alpha$ with nonzero $\alpha \in H_2(X_0)$. In this section we prove Theorem 4.1, which relates $n_b$ to certain closed Gromov–Witten invariants, which can then be computed by usual localization techniques.

Suppose we would like to compute $n_b$ for $b = \beta_i + \alpha$, and without loss of generality let’s take $i = 0$ and assume that $D_0$ is a compact toric divisor. We construct a toric compactification $X$ of $X_0$ as follows. Let $v_0$ be the primitive generator corresponding to $D_0$, and we take $\Sigma$ to be the refinement of $\Sigma_0$ by adding the ray generated by $v_\infty := -v_0$ (and then completing it into a convex fan). We denote by $X = X_\Sigma$ the corresponding toric variety, which is a compactification of $X_0$. We denote by $h \in H_2(X, \mathbb{Z})$ the fiber class of $X$, which has the property that $h \cdot D_0 = h \cdot D_\infty = 1$ and $h \cdot D = 0$ for all other irreducible toric divisors $D$. Then for $\alpha \in H_2(X_0, \mathbb{Z})$, we have the ordinary Gromov–Witten invariant $\langle [\text{pt}] \rangle_{0,1,h+\alpha}^X$.

When $X_0 = K_S$ for a toric Fano surface $S$ and $D_0$ is the zero section of $K_S \to S$, by comparing the Kuranishi structures on moduli spaces, it was shown by Chan [3] that the open Gromov–Witten invariant $n_b$ indeed agrees with the closed Gromov–Witten invariant $\langle [\text{pt}] \rangle_{0,1,h+\alpha}^X$.

**Proposition 4.2** ([3]). Let $X_0 = K_S$ for a toric Fano surface $S$ and $X$ be the fiberwise compactification of $X_0$. Let $b = \beta_i + \alpha$ with $\beta_i \cdot S = 1$ and $\alpha \in H_2(S, \mathbb{Z})$. Then

$$n_b = \langle [\text{pt}] \rangle_{0,1,h+\alpha}^X.$$

Indeed his proof extends to our setup without much modification, and for the sake of completeness we show how it works:

**Proposition 4.3** (slightly modified from [3]). Let $X_0$ be a toric Calabi–Yau manifold and $X$ be its compactification constructed above. Let $b = \beta_i + \alpha$ with $\beta_i \cdot S = 1$ and $\alpha \in H_2(S, \mathbb{Z})$, and we assume that all rational curves in $X$ representing $\alpha$ are contained in $X_0$. Then

$$n_b = \langle [\text{pt}] \rangle_{0,1,h+\alpha}^X.$$

**Proof.** For notation simplicity let $M_{\text{op}} := \overline{M}_1(X_0, b)$ be the open moduli and $M_{\text{cl}} := \overline{M}_1(X, h+\alpha)$ be the corresponding closed moduli. By evaluation at the marked point we have a $\mathbf{T}$-equivariant fibration

$$\text{ev} : M_{\text{op}} \to \mathbf{T},$$
whose fiber at \( p \in T \subset X_0 \) is denoted as \( M^{ev=p}_{op} \). Similarly we have a \( T_{C} \)-equivariant fibration

\[
ev : M_{cl} \to \bar{X},
\]

whose fiber is \( M^{ev=p}_{cl} \). By the assumption that all rational curves in \( X \) representing \( \alpha \) is contained in \( X_0 \), one has

\[
M^{ev=p}_{op} = M^{ev=p}_{cl}.
\]

There is a Kuranishi structure on \( M^{ev=p}_{cl} \) which is induced from that on \( M_{cl} \) (please refer to \([11, 10]\) for the definitions of Kuranishi structures). Transversal multisections of the Kuranishi structures give the virtual fundamental cycles \( [M_{op}] \in H_n(X, \mathbb{Q}) \) and \([M^{ev=p}_{op}] = H_0(\{p\}, \mathbb{Q}) \). In the same way we obtain the virtual fundamental cycles \([M_{cl}] \in H_{2n}(X, \mathbb{Q}) \) and \([M^{ev=p}_{cl}] \in H_0(\{p\}, \mathbb{Q}) \). By taking the multisections to be \( T_{C} \)-\((T-)\) equivariant so that their zero sets are \( T_{C} \)-\((T-)\) invariant,

\[
\deg[M^{ev=p}_{cl/op}] = \deg[M_{cl/op}]
\]

and thus it remains to prove that the Kuranishi structures on \( M^{ev=p}_{cl} \) and \( M^{ev=p}_{op} \) are the same.

Let \([u_{cl}] \in M^{ev=p}_{cl} \), which corresponds to an element \([u_{op}] \in M^{ev=p}_{op} \), \( u_{cl} : (\Sigma, q) \to X \) is a stable holomorphic map with \( u_{cl}(q) = p \). \( \Sigma \) can be decomposed as \( \Sigma_0 \cup \Sigma_1 \), where \( \Sigma_0 \cong \mathbb{P}^1 \) such that \( u_*[\Sigma_0] \) represents \( h \), and \( u_*[\Sigma_1] \) represents \( \alpha \). Similarly the domain of \( u_{op} \) can be decomposed as \( \Delta \cup \Sigma_1 \), where \( \Delta \subset C \) is the closed unit disk.

We have the Kuranishi chart \((V_{cl}, E_{cl}, \Gamma_{cl}, \psi_{cl}, s_{cl})\) around \( u_{cl} \in M^{ev=p}_{cl} \), where we recall that \( E_{cl} \oplus \text{Im}(D_{u_{cl}}\bar{\partial}) = \Omega^{(0,1)}(\Sigma, u_{cl}^*TX) \) and \( V_{cl} = \{ \bar{\partial}f \in E; f(q) = p \} \). On the other hand let \((V_{op}, E_{op}, \Gamma_{op}, \psi_{op}, s_{op})\) be the Kuranishi chart around \( u_{op} \in M^{ev=p}_{op} \).

Now comes the key: since the obstruction space for the deformation of \( u_{cl}|_{\Sigma_0} \) is 0, \( E_{cl} \) is of the form \( 0 \oplus E' \subset \Omega^{(0,1)}(\Sigma_0, u_{cl}|_{\Sigma_0}^*TX) \times \Omega^{(0,1)}(\Sigma_1, u_{cl}|_{\Sigma_1}^*TX) \). Similarly \( E_{op} \) is of the form \( 0 \oplus E'' \subset \Omega^{(0,1)}(\Delta, u_{op}|_{\Delta}^*TX) \times \Omega^{(0,1)}(\Sigma_1, u_{op}|_{\Sigma_1}^*TX) \). But since \( D_{u_{cl}|_{\Sigma_1}}\bar{\partial} = D_{u_{op}|_{\Sigma_1}}\bar{\partial}, E' \) and \( E'' \) can be taken as the same subspace! Once we do this, it is then routine to see that \((V_{cl}, E_{cl}, \Gamma_{cl}, \psi_{cl}, s_{cl}) = (V_{op}, E_{op}, \Gamma_{op}, \psi_{op}, s_{op}) \). \( \square \)

**Theorem 4.1.** Let \( X_0 \) be a toric Calabi–Yau threefold and denote by \( S \) the union of its compact toric divisors. Let \( L \) be a Lagrangian torus fiber and \( b = \beta + \alpha \in \pi_2(X_0, L) \), where \( \alpha \in H_2(S) \) is represented by a rational curve and \( \beta \in \pi_2(X_0, L) \) is one of the basic disk classes.

Given this set of data, there exists a toric Calabi–Yau threefold \( W_0 \) with the following properties:

1. \( W_0 \) is birational to \( X_0 \).
2. Let \( S_1 \subset W_0 \) be the union of compact divisors of \( W_0 \). Then \( S_1 \) is the blowup of \( S \) at one point.
3. Denote by \( \alpha' \in H_2(S_1) \) the class of strict transform of the rational curve representing \( \alpha \in H_2(S) \). Assume that every rational curve representative of \( \alpha' \) in \( W_0 \) lies in \( S_1 \). Then the open Gromov–Witten invariant \( n_b \) of \( X_0, L \) is equal to the ordinary Gromov–Witten invariant \( \langle 1 \rangle^{W_0}_{0,0,\alpha'} \) of \( W_0 \), that is,

\[
n_b = \langle 1 \rangle^{W_0}_{0,0,\alpha'}.
\]
In particular for $X_0 = K_S$, $W_0$ is $K_S$ by this construction, and so we obtain Theorem 1.1 as its corollary.

Proof. We first construct the toric variety $W_0$. To begin with, let $D_\infty$ be the toric divisor corresponding to $v_\infty$. Let $x \in X$ be one of the torus-fixed points contained in $D_\infty$. First we blow up $x$ to get $X_1$, whose fan $\Sigma_1$ is obtained by adding the ray generated by $w = v_\infty + u_1 + u_2$ to $\Sigma$, where $v_\infty$, $u_1$ and $u_2$ are the normal vectors to the three facets adjacent to $x$. There exists a unique primitive vector $u_0 \neq w$ such that $\{u_0, u_1, u_2\}$ generates a simplicial cone in $\Sigma_1$ and $u_0$ corresponds to a compact toric divisor of $X_1$: If $\{v_0, u_1, u_2\}$ spans a cone of $\Sigma_1$, then take $u_0 = v_0$; otherwise since $\Sigma_1$ is simplicial, there exists a primitive vector $u_0 \subset \mathbb{R}\langle v_0, u_1, u_2 \rangle$ with the required property. Now $\langle u_1, u_2, w \rangle$ and $\langle u_1, u_2, u_0 \rangle$ form two adjacent simplicial cones in $\Sigma_1$, and we may employ a flop to obtain a new toric variety $W$, whose fan $\Sigma_W$ contains the adjacent cones $\langle w, u_0, u_1 \rangle$ and $\langle w, u_0, u_2 \rangle$ (see Figure 1).

$W$ is the compactification of another toric Calabi–Yau $W_0$ whose fan is constructed as follows: First we add the ray generated by $w$ to $\Sigma_0$, and then we flop the adjacent cones $\langle w, u_1, u_2 \rangle$ and $\langle u_0, u_1, u_2 \rangle$. $W_0$ is Calabi–Yau because

$$(\nu, w) = 1$$

and a flop preserves this Calabi–Yau condition. $\Sigma_W$ is recovered by adding the ray generated by $v_\infty$ to the fan $\Sigma_{W_0}$.

Now we analyze the transform of classes under the above construction. The class $h \in H_2(X, \mathbb{Z})$ can be written as $h' + \delta$, where $h' \in H_2(X, \mathbb{Z})$ is the class corresponding to the cone $\langle u_1, u_2 \rangle$ of $\Sigma$ and $\delta \in H_2(X_0, \mathbb{Z})$. Let $h'' \in H_2(X_1, \mathbb{Z})$ be the class corresponding to $\{u_1, u_2\} \subset \Sigma_1$, which is flopped to $e \in H_2(W, \mathbb{Z})$ corresponding to the cone $\langle w, u_0 \rangle$ of $\Sigma_W$. Finally, let $\tilde{\delta}, \tilde{\alpha} \in H_2(W, \mathbb{Z})$ be classes corresponding to $\delta, \alpha \in H_2(X_1, \mathbb{Z})$, respectively, under the flop. Then $\alpha' = \tilde{\delta} + \tilde{\alpha} - e$ is actually the strict transform of $\alpha$.

Applying Proposition 4.3 and Theorem 1.2, we obtain the equality

$$n_b = \langle 1 \rangle^W_{0,0,\alpha'}. $$

Finally, we give an example to illustrate the open Gromov–Witten invariants.

Example 4.1. Let $X_0 = K_{\mathbb{P}^2}$. There is exactly one compact toric divisor $D_0$ which is the zero section of $X_0 \to \mathbb{P}^2$. The above construction gives $W_0 = K_{\mathbb{F}_1}$ (Figure 2). Let $\alpha = kl \in H_2(X_0, \mathbb{Z})$, where $l$ is the line class of $\mathbb{P}^2 \subset K_{\mathbb{P}^2}$ and $k > 0$. By Theorem 4.1,

$$n_{\beta_0 + kl} = \langle 1 \rangle^W_{0,0,kl} = \langle 1 \rangle^W_{0,0,kf+(k-1)e}. $$
where \( e \) is the exceptional class of \( F_1 \subset K_{\mathbb{P}^1} \) and \( f \) is the fiber class of \( F_1 \to \mathbb{P}^1 \). The first few values of these local invariants for \( K_{\mathbb{P}^1} \) are listed in Table 1.

5. A generalization to \( \mathbb{P}^n \)-bundles

In this section, we generalize Theorem 1.2 to higher dimensions, that is, to \( \mathbb{P}^n \)-bundles over an arbitrary smooth projective variety.

Let \( X \) be an \( n \)-dimensional smooth projective variety. Let \( F \) be a rank \( r \) vector bundle over \( X \) with \( 1 \leq r < n \). Let \( p : W = \mathbb{P}(F \oplus O_X) \to X \) be a \( \mathbb{P}^r \)-bundle over \( X \). There are two canonical subvarieties of \( W \), say \( W_0 = \mathbb{P}(0 \oplus O_X) \) and \( W_\infty = \mathbb{P}(F \oplus 0) \). We have \( W_0 \cong X \).

Let \( S \subset X \) be a smooth closed subvariety of codimension \( r + 1 \) with normal bundle \( N \). Let \( \pi : \tilde{X} \to X \) be the blowup of \( X \) along \( S \) with exceptional divisor \( E = \mathbb{P}(N) \). Then \( F' = \pi^*F \otimes O_{\tilde{X}}(E) \) is a vector bundle of rank \( r \) over \( \tilde{X} \). Similar to \( p : W \to X \), we let \( p' : W' = \mathbb{P}(F' \oplus O_{\tilde{X}}) \to \tilde{X} \).

It is easy to see that \( W \) and \( W' \) are birational. We shall construct an explicit birational map \( g : W \dashrightarrow W' \). It induces a homomorphism between groups

\[
g'_* : H_2(W, \mathbb{Z}) \to H_2(W', \mathbb{Z}).
\]

Let \( \beta = h + \alpha \in H_2(W, \mathbb{Z}) \) with \( h \) the fiber class of \( W \) and \( \alpha \in H_2(X, \mathbb{Z}) \). Then we establish a relation between certain Gromov–Witten invariants of \( W \) and \( W' \).

**Proposition 5.1.** Let \( Y = \mathbb{P}(F_S \oplus 0) \subset W \). For \( g : W \dashrightarrow W' \), we have

\[
\langle \gamma_1, \gamma_2, \cdots, \gamma_m-1, PD([Y]) \rangle^W_{0,m,\beta} = \langle \gamma'_1, \cdots, \gamma'_m-1 \rangle^W_{0,m-1,\beta'}.
\]

Here \( \gamma'_i \) is the image of \( \gamma_i \) under \( H^*(W) \to H^*(W') \) and \( \beta' = g'_*(\beta) \).

The birational map \( g : W \dashrightarrow W' \) we shall construct below can be factored as

\[
W \xrightarrow{\pi^{-1}} \tilde{W} \xrightarrow{f} W'.
\]

Here \( \pi_1 : \tilde{W} \to W \) is a blowup along a subvariety \( Y \). We make the following assumption:

(A) Let \( \beta = h + \alpha \in H_2(W, \mathbb{Z}) \) with \( h \) the fiber class of \( W \) and \( \alpha \in H_2(X, \mathbb{Z}) \). Every curve \( C \) in class \( \beta \) can be decomposed uniquely as \( C = H \cup C' \) with \( H \) a fiber and \( C' \) a curve in \( X \).

It follows that the intersection of \( C \) and \( Y \) is at most one point. Under this assumption we generalize Theorem 2.1 in a straightforward manner as follows.

![Figure 2. Polytope picture for \( K_{\mathbb{P}^2} \) and \( K_{\mathbb{P}^3} \)](image-url)
Proposition 5.2. Let the notation be as above. Let $E'$ be the exceptional divisor of $\pi_1$. Let $e$ be the line class in the fiber of $E' \to Y$. Suppose the assumption (A) holds, we have
\[
\langle \tilde{\gamma}_1, \tilde{\gamma}_2, \ldots, \tilde{\gamma}_{m-1}, PD([Y]) \rangle_{0,m,\beta}^W = \langle \tilde{\gamma}_1, \ldots, \tilde{\gamma}_{m-1} \rangle_{0,m-1,\beta_1}^W,
\]
where $\tilde{\gamma}_i = \pi_1^*\gamma_i$ and $\beta_1 = \pi_1'(\beta) - e$.

The proof of Proposition 5.1 is similar to that of Theorem 1.2.

Proof of Proposition 5.1. Since $g = f\pi_1^{-1}$, applying Proposition 5.2, it suffices to show
\[
\langle \tilde{\gamma}_1, \ldots, \tilde{\gamma}_{m-1} \rangle_{0,m-1,\beta_1}^{W'} = \langle \tilde{\gamma}_1', \ldots, \tilde{\gamma}_{m-1}' \rangle_{0,m-1,\beta_1}'
\]
for the ordinary flop $f : \tilde{W} \to W'$.

Recall that Lee et al. [16] proved that for an ordinary flop $f : M \to M_f$ of splitting type, the big quantum cohomology rings of $M$ and $M_f$ are isomorphic. In particular, their Gromov–Witten invariants for the corresponding classes are the same. Therefore, the above identity follows. □

In the rest of the section, we construct the birational map $g : W \to W'$ in two equivalent ways.

Recall that $S \subset X$ is a subvariety. Let $p_S : Z = W \times_X S \to S$ be the restriction of $p : W \to X$ to $S$. Then $Z = P(F_S \oplus \mathcal{O}_S)$ with $F_S$ the restriction of $F$ to $S$. We denote $Y = Z \cap W_\infty = P(F_S \oplus 0)$, and $q : Y \to S$ the restriction of $p_S$ to $Y$. Since $Y$ is a projective bundle over $S$, we let $\mathcal{O}_{Y/S}(-1)$ be the tautological line bundle over $Y$. The normal bundle of $Y$ in $Z$ is $N_{Y/Z} = \mathcal{O}_{Y/S}(1)$.

We start with the first construction of $g$. Let $\pi_1 : \tilde{W} \to W$ be the blowup of $W$ along $Y$. Since the normal bundle $N_{Y/W}$ is equal to $N_{Y/Z} \otimes N_{Y/W_\infty} = \mathcal{O}_{Y/S}(1) \otimes q^*N$, the exceptional divisor of $\pi_1$ is
\[
E' = P(\mathcal{O}_{Y/S}(1) \oplus q^*N).
\]
Let $\tilde{Z}$ be the proper transform of $Z$ and $\tilde{Y} = \tilde{Z} \cap E'$. The normal bundle of $\tilde{Z}$ in $\tilde{W}$ is $\tilde{N} = p_S^*N \otimes \mathcal{O}_{\tilde{Z}}(-\tilde{Y})$.

Because $Z' \cong Z$ is a $\mathbb{P}^r$-bundle over $S$, and the restriction of $\tilde{N}$ to each $\mathbb{P}^r$-fiber of $\tilde{Z}$ is isomorphic to $\mathcal{O}(-1)^{\oplus r+1}$, we have an ordinary $\mathbb{P}^r$-flop $f : W' \to \tilde{W}_f$ along $\tilde{Z}$. It can be verified that $\tilde{W}_f = W'$ after decomposing $f$ as a blowup and a blowdown. Finally we simply define $g$ as the composite $f\pi_1^{-1} : W \to W'$.

We describe the second construction of $g$, from which it is easy to see the relation $\tilde{W}_f = W'$.

We let $\rho_1 : W_1 \to W$ be the blowup of $W$ along $Z$ whose exceptional divisor is denoted by $E_1$. Because the normal bundle of $Z$ in $W$ is $q^*N$ for $q : Z \to S$, we know
\[
E_1 = P(q^*N) \cong Z \times_S \mathbb{P}(N) = Z \times_S E.
\]
Indeed, $W_1$ is isomorphic to the $\mathbb{P}^r$-bundle $P(F_1 \oplus \mathcal{O}_{\tilde{X}})$ over $\tilde{X}$ with $F_1 = \pi_1^*F$. Let $Y_1$ be the inverse image of $Y$. Now we let $\rho_2 : W_2 \to W_1$ be the blowup of $W_1$ along $Y_1$ with exceptional divisor $E_2$. Let $E_1'$ be the proper transform of $E_1$ and $Y_2 = E_1' \cap E_2$. Notice that $E_1' \cong E_1$, and the normal bundle of $E_1$ is $N_1 = q^*N \otimes \mathcal{O}_{E_1/S}(-1)$, we know the normal bundle of $E_1'$ is $N_1' = N_1 \otimes \mathcal{O}_{E_1}(-Y_2)$. 

Since $E_1' \cong Z \times_S E$ is a $\mathbb{P}^r \times \mathbb{P}^r$-bundle over $S$, composed with the projection $Z \times_S E \to E$, we see that $E_1' \to E$ is a $\mathbb{P}^r$-bundle. Because the restriction of $N_1'$ to the $\mathbb{P}^r$-fiber of $E_1' \to E$ is isomorphic to $\mathcal{O}(-1)^{\oplus r+1}$, we can blowdown $W_2$ along these fibers of $E_1'$ to get $\pi_3 : W_2 \to W_3 = \tilde{W}_f$. From this description it is easy to see that $W_3 = W'$. 

Acknowledgments

We thank Kwokwai Chan for stimulating discussions and his preprint [3] on the comparison of Kuranishi structures. His ideas on the relationship between open Gromov–Witten invariants and mirror periods inspired our work. The first author is very grateful to Mark Gross for enlightening discussions on wall-crossing and periods. The first and second author would like to thank Andrei Căldăraru and Yong-Geun Oh for their hospitality and joyful discussions at University of Wisconsin, Madison. We also thank Jianxun Hu for helpful comments. The work of the authors described in this paper was partially supported by a grant from the Research Grants Council of the Hong Kong Special Administrative Region, China (Project no. CUHK401809).
